The classical Chern-Gauss-Bonnet theorem gives a relationship between the Euler characteristic of a manifold and local curvature quantities:

Theorem

Let (\mathbb{M}, g) be a compact, even-dimensional, orientable Riemannian manifold without boundary and let Ω be the curvature form of some metric connection ∇ . Then

$$\int_{\mathbb{M}} \frac{1}{(2\pi)^n} \det(\Omega)^{1/2} = \chi(\mathbb{M})$$

Vega-Molino

Totally-
geodesic
foliations

Horizontal
Laplacian on
forms

Horizontal
McKean-
Singer
Theorem

Short-time
Asymptotics

Let (\mathbb{M}, g) be a smooth $n + m$ dimensional Riemannian manifold equipped with a foliation with m -dimensional leaves.

- We call the subbundle \mathcal{V} tangent to the leaves vertical.
- Let \mathcal{H} be a transverse, bracket-generating subbundle (called horizontal).

vector fields $X \in \Gamma(\mathcal{H}), Z \in \Gamma(\mathcal{V})$, we insist that the foliation is

- Riemannian:

$$(\mathcal{L}_Z g)(X, X) = 0$$

- Totally-geodesic:

$$(\mathcal{L}_X g)(Z, Z) = 0$$

Laplacian on
forms

Horizontal
McKean-
Singer
Theorem

Short-time
Asymptotics

There exists a unique metric connection ∇ on (\mathbb{M}, g) such that

- 1 \mathcal{H} and \mathcal{V} are ∇ -parallel,
- 2 The torsion T of ∇ satisfies
 - $T(\mathcal{H}, \mathcal{H}) \subset \mathcal{V}$,
 - $T(\mathcal{V}, \mathcal{V}) \subset \mathcal{H}$
- 3 For every $X, Y \in \Gamma(\mathcal{H}), Z, V \in \Gamma(\mathcal{V})$,
 - $\langle T(X, Z), Y \rangle_{\mathcal{H}} = \langle T(Y, Z), X \rangle_{\mathcal{H}}$
 - $\langle T(Z, X), V \rangle_{\mathcal{V}} = \langle T(V, X), Z \rangle_{\mathcal{V}}$.

This is called the Bott connection.

Hladky-Bott Connection

We can determine ∇ using the Levi-Civita connection ∇^g as

$$\nabla_X Y = \begin{cases} \pi_{\mathcal{H}} \nabla_X^g Y & X, Y \in \Gamma(\mathcal{H}) \\ \pi_{\mathcal{H}}[X, Y] & Y \in \Gamma(\mathcal{H}), X \in \Gamma(\mathcal{V}) \\ \pi_{\mathcal{V}}[X, Y] & Y \in \Gamma(\mathcal{V}), X \in \Gamma(\mathcal{H}) \\ \pi_{\mathcal{V}} \nabla_X^g Y & X, Y \in \Gamma(\mathcal{V}) \end{cases}$$

which has torsion

$$T(X, Y) = -\pi_{\mathcal{V}}[\pi_{\mathcal{H}}X, \pi_{\mathcal{H}}Y]$$

Theorem

Short-time
Asymptotics

We can associate to each vector field $Z \in \Gamma(TM)$ an endomorphism J_Z of TM defined by

$$\langle J_Z X, Y \rangle = \langle Z, T(X, Y) \rangle$$

which can be viewed as

$$J: \mathcal{V} \rightarrow \mathbf{End}(\mathcal{H}), \quad Z \mapsto J_Z$$

Canonical variation metric

We consider the family of metrics parameterized by $\varepsilon > 0$

$$g^\varepsilon = g_{\mathcal{H}} \oplus \frac{1}{\varepsilon} g_{\mathcal{V}}$$

and observe:

- If (\mathbb{M}, g) is a totally-geodesic, Riemannian foliation, so is $(\mathbb{M}, g^\varepsilon)$.
- The connection

$$\hat{\nabla}_X^\varepsilon Y := \nabla_X Y + \frac{1}{\varepsilon} J_X Y$$

is metric, preserves \mathcal{H}, \mathcal{V} , and is also $g^{\varepsilon'}$ -metric for any $\varepsilon' > 0$.

- The adjoint connection

$$\nabla_X^\varepsilon Y := \hat{\nabla}_X^\varepsilon Y - \hat{T}^\varepsilon(X, Y)$$

is also metric.

We now introduce our notion of horizontal Laplacian. On functions $f \in C^\infty(\mathbb{M})$, we define

$$\Delta_{\mathcal{H}}f = \operatorname{tr}_{\mathcal{H}} \nabla_{\times} df(\times)$$

- \mathcal{H} bracket generating and Hormander's condition imply that $\Delta_{\mathcal{H}}$ is hypoelliptic.
- Since \mathcal{H} and $g_{\mathcal{H}}$ are independent of ε (with respect to the metric, g^ε), so is $\Delta_{\mathcal{H}}$.

Singer
Theorem

Short-time
Asymptotics

We desire a horizontal Laplacian $\Delta_{\mathcal{H},\varepsilon}$ acting on differential forms satisfying the following:

- $\Delta_{\mathcal{H},\varepsilon} f = \Delta_{\mathcal{H}} f$ for smooth functions f .
- Weitzenböck type:

$$\Delta_{\mathcal{H},\varepsilon} = \text{tr}_{\mathcal{H}} \tilde{\nabla}_{X,X}^2 + \mathcal{R}_{\varepsilon}$$

with $\tilde{\nabla}$ some g^{ε} -metric connection and $\mathcal{R}_{\varepsilon}$ a zeroth-order operator.

- Commutativity with exterior derivative:

$$[\Delta_{\mathcal{H},\varepsilon}, d] = 0$$

Horizontal
McKean-
Singer
Theorem

Short-time
Asymptotics

First, we justify the existence of the heat semigroup $e^{t\Delta_{\mathcal{H},\varepsilon}}$ by noting that $\Delta_{\mathcal{H},\varepsilon}$ commutes with the Hodge-deRham Laplacian

$$\Delta_{\varepsilon} = -d\delta_{\varepsilon} - \delta_{\varepsilon}d$$

and that for any λ -eigenspace E_{λ} of Δ_{ε} it must hold that

$$\Delta_{\mathcal{H},\varepsilon}(E_{\lambda}) \subset E_{\lambda}$$

which implies that $\Delta_{\mathcal{H},\varepsilon}$ is essentially self-adjoint and generates a semigroup with heat kernel $p_{\mathcal{H},\varepsilon}$.

Collecting the results,

Theorem

If either $n = \text{rank } \mathcal{H}$, $m = \text{rank } \mathcal{V}$ are odd, then $\chi(\mathbb{M}) = 0$. If they are both even then

$$\chi(\mathbb{M}) = \int_{\mathbb{M}} \hat{\omega}_{\mathcal{H}}^{\varepsilon} \wedge \left[\det \left(\frac{\mathcal{T}}{\sinh \mathcal{T}} \right)^{1/2} \right]_m .$$

We emphasize that this expression depends only on horizontal curvature quantities, and can be understood as a purely sub-Riemannian result.
